

**Figure 6: Post-treatment lateral cephalometric radiograph.** Post-treatment cephalometric radiograph demonstrates a significant improvement in the sagittal skeletal relationship, with counterclockwise rotation of the mandible and clockwise rotation of the occlusal plane. Sagittal and vertical relation of the mandible in comparison with the maxilla significantly improved. Regarding dental inclinations, the maxillary anterior position was maintained while the mandibular incisors were slightly retroclined. These skeletal and dental changes significantly enhanced the soft-tissue profile, particularly the lower lip position.
